This circular was prepared by K. A. Kelley, Assistant Agronomist; R. W. Esgar, Associate Agronomist; E. D. Nafziger, Associate Professor of Agronomy Extension, C. A. Smyth, Research Specialist (Statistics and Computing); and L. T. Smith, Graphic Artist.

# PERFORMANCE OF COMMERCIAL CORN AND SORGHUM HYBRIDS IN ILLINOIS, 1992

(With 1990 and 1991 Results)

## TEST PROGRAM

**Selection of entries.** Each year, producers of hybrid seed corn in Illinois and surrounding states are invited to enter hybrids in the Illinois performance trials. This testing program is financed by a fee of \$60 for each hybrid entered at a location. Most of these hybrids are commercially available, although a few experimental hybrids are also entered.

**Number and location of tests.** In 1992, 10 major tests were conducted at 9 locations in the state (see map). These sites represent major soil and climatic areas of the state.

**Hybrids.** There were 695 hybrids from 88 companies tested in 1992.

**Field-plot design.** Three replications of an Alpha design were used to give each entry an equal chance to show its merits.

**Planting methods.** All trials were planted by machine. All test fields except those at DeKalb and Monmouth were part of larger cornfields and thus were bordered by other corn. Each hybrid plot was overplanted 30 percent and later thinned to desired stands. Each plot was four rows wide and 25 feet long. The center two rows of each plot were harvested to determine yields.

**Fertilization.** All test fields were at a high level of fertility. Additional fertilizer was plowed down or sidedressed as needed to ensure top yields.

**Method of harvest.** All plots were harvested with a custom-built, self-propelled, corn plot combine. Shelled corn from each plot was collected, weighed, and tested for moisture content. No allowance was made for corn that might have been lost in harvest.

## PERFORMANCE DATA

**Grain yield.** Shelled-corn weight and moisture percentage were measured for each plot of a hybrid and converted to bushels per acre of No. 2 shelled corn (15.5 percent moisture). An electronic moisture monitor was used in the combine for all moisture readings.

**Moisture content.** Occasionally, hybrids too late in maturity for a given area are entered in these tests. These hybrids are often high in yield, but their moisture content may make them poor choices for farm use unless proper drying or storage facilities are available.

**Erect plants.** The number of erect plants in each plot of a hybrid was determined at harvest time. Any plant leaning at an angle of more than 45 degrees or broken below the ear was considered lodged. Plants broken above the ear were considered erect.

**Population.** In late June, plants in all plots on all fields were counted and populations computed. Plots with over 100 percent of the desired population were thinned at that time. Stand differences may be caused by failure to germinate or by damage from diseases, insects, cultivation, or rodents.

## SUGGESTIONS FOR COMPARING HYBRIDS

It is impossible to measure performance exactly in any test of plant material. Harvesting efficiency may vary, soils may not be uniform, and many other conditions may produce variability. Results of repeated tests, like those reported here, are more reliable than those of a single-year or a single-strip test. When one hybrid consistently outyields another at several test locations and over several years of testing, the chances are good that this difference is real and should be a consideration in choosing a hybrid. When comparing yields, however, grain moisture content, percentage of erect plants, and plant population must also be considered.

A number of statistical tests are available for comparing hybrids within a single trial. One of these tests, the least significant difference (L.S.D.), when used in the manner suggested by Carmer and Swanson,<sup>1</sup> is quite simple to apply and is more appropriate than most other tests. When two hybrids are compared and the difference between them is greater than the tabulated L.S.D. value, the hybrids are judged "significantly different."

When the observed mean of hybrid A is larger than that of hybrid B and the difference between them is found to be significant, one of three possibilities has occurred: (1) the mean of hybrid A really is larger than that of hybrid B, and a correct decision has been made; (2) the means of hybrids A and B are really equal, and a Type I statistical error has been made (that is, the means were declared to be unequal when they were actually equal); or (3) the mean of hybrid B is really larger than that of hybrid A, and a reverse decision or Type III statistical error has been made (that is, the mean of A was declared to be greater than that of B, when the reverse is true).

When no significant difference is found between two hybrids, one of two possibilities has occurred: (1) the means are really equal, and a correct decision has been made; or (2) the means are really different, and a Type II statistical error has been made (that is, the means were declared to be equal when they really are different). In a study of the frequencies of occurrence of these three types of statistical errors and their relative seriousness, Carmer<sup>2</sup> found strong arguments for an optimal significance level in the range  $\alpha = 0.20$  to  $0.40$ , where  $\alpha$  is the Type I statistical error rate for comparisons between means that are really equal. Herein, values of  $\alpha = 0.10$  and  $0.30$  are used in computing the L.S.D. 10- and 30-percent levels shown in the tables. L.S.D. 10 and L.S.D. 30 are not calculated when the overall F test of differences among entries is not significant at the 5 percent level.

To make the best use of the information presented in this circular and to avoid any misunderstanding or misrepresentation of it, the reader should consider an additional caution about comparing hybrids. Readers who compare hybrids in different

trials should be extremely careful, because no statistical tests are presented for that purpose. Readers should note that the difference between a single hybrid's performance at one location and its performance at another is caused primarily by environmental effects and random variability. Furthermore, the difference between the performance of hybrid A in one trial and that of hybrid B in another is the result not only of environmental effects and random variability, but of genetic effects as well.

### 1992 GROWING CONDITIONS

All corn plots were planted by May 12. In Northern Illinois emergence was slow due to cold and dry conditions after planting. Some frost damage was noted at Woodstock, DeKalb, Dwight and Monmouth. High yields at most locations can be attributed to timely rains during the months of June and July. Cool summer temperatures slowed plant maturity and harvest was started late. All locations were harvested in a timely manner, however, high grain moisture and rainfall in November may delay harvest at Woodstock and DeKalb until December.

### SUMMARY OF ILLINOIS HYBRID CORN TESTS, 1992

Field, County, location and number of entries	Date planted	Date harvested	Avg. yld (B/A)	Grain mst. (%)	Erect plants (%)	Avg. pop. (plt/A)
<b>30-inch rows, 22,000 plants per acre</b>						
Brownstown: Fayette, S, 150	5-11	10-7,8	138	25.2	98	21,893
Ina: Jefferson, Ex.S, 88	5-11	10-9	76	23.7	98	21,962

## 1992 TEST FIELDS

### Woodstock

Location: Northeastern Illinois (cool, humid).  
 Soil type: Proctor silt loam (fertile, deep, well-drained, dark prairie).  
 Planting date: May 5.  
 Harvest date: December 2.  
 Cooperators: Hughes Farms and Seed Company; Robert Hughes and Earl Hughes, Jr.

### DeKalb

Location: University of Illinois, Northern Illinois Research Center, southwest of DeKalb.  
 Soil type: Flanagan silt loam (dark brown, adequately drained, highly fertile).  
 Planting date: May 4.  
 Harvest date: November 18, December 1.  
 Cooperators: Lyle Paul, research director; David Lindgren, farm foreman.

### Dwight

Location: Livingston County.  
 Soil type: Elliott silty clay loam.  
 Planting date: April 27 & 28.  
 Harvest date: October 22 & 23.  
 Cooperator: Larry Zabel.

### Monmouth

Location: University of Illinois, Northwestern Illinois Agricultural Research and Demonstration Center.  
 Soil type: Muscatine silt loam.  
 Planting date: April 30.  
 Harvest date: October 20 & 21.  
 Cooperator: Mike Mainz, research director.

### Urbana

Location: University of Illinois Agronomy South Farm, Champaign County, east central Illinois.  
 Soil type: Flanagan silt loam.  
 Planting date: May 6 & 7.  
 Harvest date: October 14, 18 & 19.  
 Cooperators: Gene Oldham, superintendent; Mike Plotner, farm foreman.

### Perry

Location: Orr Research Center, Pike County, south central Illinois.  
 Soil type: Rozetta silt loam.  
 Planting date: May 1.  
 Harvest date: October 5 & 6.  
 Cooperators: Glenn Raines, research director; Mike Vose, farm foreman.

### Brownstown

Location: University of Illinois, Brownstown Experimental Field, Fayette County, south central Illinois.  
 Soil type: Cisne silt loam.  
 Planting date: May 11.  
 Harvest date: October 7 & 8.  
 Cooperator: Jim Carter, farm foreman.

### Ina

Location: Rend Lake College, Jefferson County, south central Illinois.  
 Soil Type: Cisne silt loam.  
 Planting date: May 11.  
 Harvest date: October 9.  
 Cooperator: Dave Scott, Coordinator for Rend Lake College.

### Dixon Springs

Location: University of Illinois Dixon Springs Agricultural Center, Pope County, extreme southern Illinois.  
 Soil types: Sharon silt loam (light-colored, moderately well drained, medium-textured bottomlands) Grantsburg (upland).  
 Planting date: May 12.  
 Harvest date: October 12 & 13.  
 Cooperators: Steve Ebelhar, research director; Ron Hines, research specialist.

## GROWING SEASON RAINFALL, 1992
